Abstract—This paper focuses on the act of using data and insights to identify how much of a specific product or service customers will want to purchase during a defined time period i.e identifying the demand of sales stock. Improper management or estimation skills could lead to problems like stock out over stock. So, to help overcome these loss causing problems, our system will help retailers understand how much stock to have at hand at a given time based on the previous data. This proposed work has implemented various clauses like partition by and row by, aggregate functions, type casts, joins, etc. We have also performed Normalization for data redundancy.

Index Terms—BCNF, Normalization, Query optimization, Triggers

I. INTRODUCTION

Every business is looking for ways to cut costs. In a business, demand forecasting uses facts and understandings to identify the need of a specific item or service customers tend to buy during a specific time interval. This gives businessmen an idea of the stock to be maintained at a particular period. When we implement a proper methodology to your business, we are cutting costs in a few ways. Firstly, we are reducing the amount of capital we have tied up in unneeded inventory. And the less stock on hand we have, the lower our holding costs. Secondly, we are making sure you capitalize on every sale opportunity by not disappointing customers with out of stocks. Additionally, businesses are expanding on a large scale. With this increasing competition, every business should cope up with the increasing demand by considering various factors like time and seasonality of goods.

Sales analysis helps determine production volume by taking into account capital, manpower, available equipment etc. It is also helpful in guiding production and other business activities for achieving targets.

II. DATASET

A. Description

We have used Iowa State's liquor dataset. The Iowa Department of Commerce requires that every store that sells alcohol in bottled form for off-the-premises consumption must hold a class "E" liquor license. Liquor sales made by stores must be registered with the Iowa Department of Commerce which is then published by the state as an open data. The dataset has data from the year 2012 to 2015. Using this dataset, we can analyse and get insights of liquor sales in Iowa state and can

be representative of sale activity in the United States as well. It can help answer questions like how much alcohol is sold in a particular time period? Most popular alcohols? Volume of liquor sold? Total vendors in a particular county? etc.

B. Data Pre-processing

The dataset was around 3.5GB which consisted of over 10 million rows. So, we split the dataset into a smaller .csv form with 20k rows for ease while using PostgreSQL. Certain, rows in .csv had store number, zip code values missing hence, we deleted those rows to weed out the missing values in the dataset. After this, we created tables to establish a schema and generated an ER diagram (Fig.1) to visualize it.

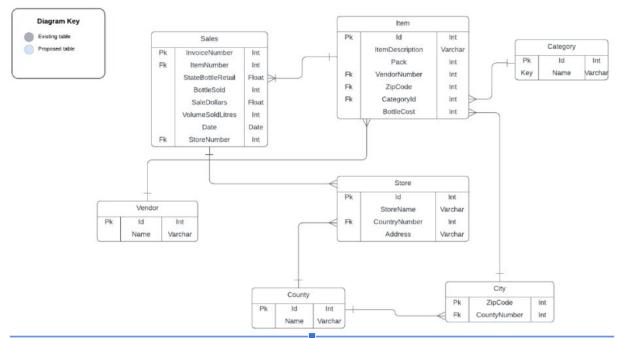

Fig. 1. Initial ER diagram.

III. NORMALIZATION

To remove redundancies from the table, we performed Normalization.

A. 1NF

A table is in 1NF if all the columns contain only atomic values. In our dataset, multi-values were not present in any column. So, the dataset was already in 1NF.

B. 2NF

Condition to be in 2NF is that the table should have no partial dependency present in it. We considered the Items Table which contained Item Number, Description, Category ID, Vendor Number, Zip code and Bottle cost. Here, Vendor number and Zip code alone could not decide the value of item. Hence, partial dependency existed and we removed them.

C. 3NF

Table is in 3NF if no transitive dependency exists for non prime attributes. The Sales table consisted of Item Number, Invoice Number, State bottle retail, Bottle sold, Sale dollars, Date, Volume sold and Store Number. Sale dollars was the product of State bottle retail and volume sold. Thus, there was Transitive dependency present which we removed and the table was now in 3NF.

D. BCNF

BCNF must satisfy two conditions:

- Table in 3NF
- For any dependency

$$X -> Y$$

X must be a Candidate or Super key.

Schema already in 3NF. All the candidate keys present has a relation with all the determinants.

- For Sales table:

$$\text{invoicenumber} -> \text{date}$$

$$\text{invoicenumber} -> \text{storenumber}$$

$$\text{invoicenumber} -> \text{vendornumber}$$

$$\text{invoicenumber} -> \text{zipcode}$$

$$\text{invoicenumber} -> \text{itemnumber}$$

$$\text{invoicenumber} -> \text{bottlesold}$$

$$\text{invoicenumber} -> \text{statebottleretail}$$

$$\text{invoicenumber} -> \text{volumesold}$$

- For Vendor table:

$$\text{vendorid} -> \text{vendornumber}$$

- For Items table:

$$\text{itemid} -> \text{itemdescription}$$

$$\text{itemid} -> \text{categoryid}$$

- For City table:

$$\text{zipcode} -> \text{countynumber}$$

- For Store table:

$$\text{id} -> \text{storename}$$

$$\text{id} -> \text{countynumber}$$

- For Address table:

$$\text{storenumber} -> \text{addressword}$$

- For County table:

$$\text{countyid} -> \text{countynumber}$$

- For Category table:

$$\text{id} -> \text{categoryname}$$

IV. RELATIONS BETWEEN TABLES

Initially, we only had one table of IOWA liquor. We converted this single table into 8 different tables to remove the redundancies present in the data. The main table of our project is the Sales table. And, after normalization, all the tables are connected using different constraints.

V. UPDATED ER DIAGRAM

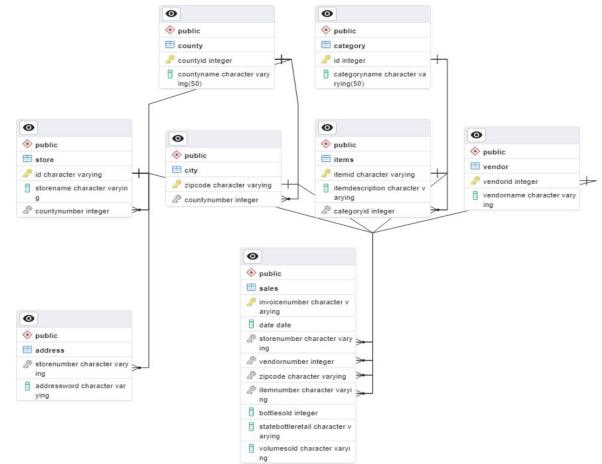

Fig. 2. Final ER Diagram

On comparing Fig. 1. and Fig. 2. we can clearly see that after performing Normalization, the ER diagram and the tables are been updated.

After Normalization we got the following tables:

- Store Table
- County Table
- Category Table
- City Table
- Items Table
- Vendor Table
- Address Table
- Sales Table

A. Table Descriptions

- Store Table: Store table has three columns with primary key as "ID" which also serves as a foreign for for Sales table. It has columns like "countynumber" and "storename". Where "countynumber" is a foreign key from County table.
- County Table: County table has two columns "countyID" and "countyname". Where "countyID" is serving as a foreign key to tables Store and Sales.
- Category Table: Category table has two columns "ID" and "categoryname". Here, "ID" is a primary key and is a foreign key to table Items.
- City Table: This has two columns "zipcode" and "countynumber". "zipcode" is a primary key here.

- Items Table: Table Items has "itemID" as a primary key and "categoryID" as a foreign key from table Category and has one more column called "itemdescription".
- Vendor Table: Vendor table has two columns "vendorID" and "vendorname". "vendorID" is a primary key and is serving as a foreign key for table Sales.
- Address Table: Has two columns "storenumber" and "address". "storenumber" is a foreign key of table Address and also a primary key for table Store.
- Sales Table: Table Sales is our primary table with 9 columns. "invoicenumber" is the primary key here which uniquely identifies as the data entries of the table. It is of integer type. The "date" column represents the purchase date of a particular product. Sales table has four foreign keys namely "storenumber", "vendornumber", "zipcode" and "itemnumber". It also has columns like "bottlesold", "retailprice" and "volumesold" which represents number of bottles sold of that particular type, retail cost of the liquor and volume in litres of liquor sold respectively.

VI. QUERY EXECUTION

1. Total sales of liquor of a single category for all the stores in descending order (Top 20)

We, used aggregate function SUM and joined two tables to find top 20 total sales of liquor of a single category for all the stores in descending order. Refer Fig. 3.

```
select sum(s.volumesold::decimal),ca.categoryname
from public.sales s join public.items i on i.itemid=s.itemnumber
join category ca on ca.id=i.categoryid
group by ca.categoryname
order by sum(s.volumesold::decimal) desc limit 20;
```

The screenshot shows a database interface with a query history tab and a data output tab. The query history tab displays the SQL code with some parts highlighted in red. The data output tab shows a table with 13 rows, each containing a category name and its total sales volume. The table is sorted by sales volume in descending order.

	categoryname	volumesold
1	VODKA 80 PROOF	37268.80
2	CANADIAN WHISKIES	23838.57
3	SPICED RUM	11699.61
4	PUERTO RICO & VIRGIN ISLANDS RUM	9582.07
5	BLENDED WHISKIES	8439.41
6	CREAM LIQUEURS	7745.47
7	STRAIGHT BOURBON WHISKIES	7013.43
8	TEQUILA	6885.73
9	WHISKEY LIQUEUR	6750.37
10	AMERICAN COCKTAILS	6430.66
11	IMPORTED VODKA	6141.36
12	VODKA FLAVORED	5461.84

Fig. 3. Total sales of liquor of a single category for all the stores in descending order

2. Highest selling category of liquor for a particular county in a particular year

Using Typecast, we converted volume sold in varchar to integer and found the highest selling liquor in Polk county in 2012. Refer Fig. 4.

```
select sum(s.volumesold::decimal),ca.categoryname
from public.sales s join public.items i on i.itemid=s.itemnumber
join city ci on ci.zipcode=s.zipcode join public.county c1
on c1.countyid=ci.countynumber join category ca
on ca.id=i.categoryid where c1.countyname='Polk' and
s.date::text like '%2012%' group by ca.categoryname, c1.countyname
order by sum(s.volumesold::decimal) desc limit 20;
```

The screenshot shows a database interface with a query history tab and a data output tab. The query history tab displays the SQL code with some parts highlighted in red. The data output tab shows a table with 13 rows, each containing a category name and its total sales volume. The table is sorted by sales volume in descending order.

	categoryname	volumesold
1	CREAM LIQUEURS	3435.60
2	VODKA 80 PROOF	1336.76
3	CANADIAN WHISKIES	856.31
4	WHISKEY LIQUEUR	721.55
5	PUERTO RICO & VIRGIN ISLANDS RUM	517.18
6	AMERICAN COCKTAILS	455.55
7	IMPORTED VODKA	391.86
8	STRAIGHT BOURBON WHISKIES	379.87
9	SPICED RUM	366.78
10	TEQUILA	307.67
11	BLENDED WHISKIES	264.07
12	MISC. IMPORTED CORDIALS & LIQUEURS	244.50
13	IMPORTED VODKA - MISC	241.05

Fig. 4. Highest selling category of liquor for a particular county in a particular year

3. Black Friday sales for individual year

Using GROUP BY and HAVING clause together, we trimmed year using substring function to find Black Friday sales for each year. Refer Fig. 5.

```
select sum(sel.bottlesold) , sel.blackfriday
from (select sum(s.bottlesold) as bottlesold,substring(s.date::varchar, 1,4)
as blackfriday from public.sales s where s.date::text like
'%group by s.date order by sum(s.bottlesold) desc) as sel
group by sel.blackfriday having sel.blackfriday::text like '%201%'
```

```

11. Highest selling category of liquor in every county

We used PARTITION BY to categorize county by their highest selling liquor using ROW NUMBER function. Refer Fig. 13.

```
select * from (select sum(s.volumesold::decimal) as volume,ca.categoryname as category, c1.countyname as countyname, ROWNUMBER() OVER (PARTITION BY c1.countyname Order by sum(s.volumesold::decimal) DESC) AS Sno from public.sales s join public.items i on i.itemid=s.itemnumber join city ci on ci.zipcode=s.zipcode join public.county c1 on c1.countyid=ci.countynumber join category ca on ca.id=i.categoryid group by ca.categoryname,c1.countyname order by countyname asc ,sum(s.volumesold::decimal) desc) a1 WHERE Sno <=1
```

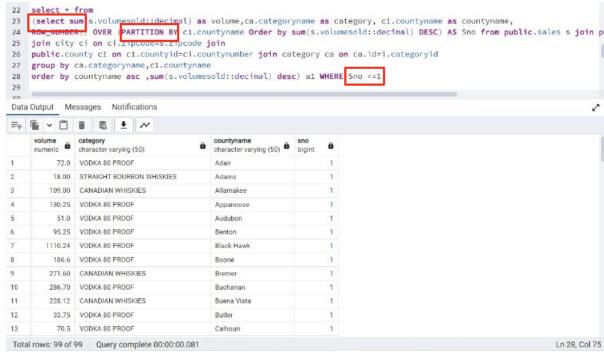

Fig. 13. Highest selling category of liquor in every county

• Query Optimization

1. Yearly liquor revenue for Iowa state

Instead of fetching daily data of each week on Black Friday from each year, we used TRIM and SUBSTRING function and subquery to calculate the retail price on Black Friday from each year. Refer Fig.14.

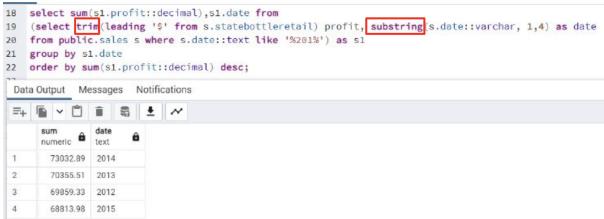

Fig. 14. Query Optimization: Yearly liquor revenue for Iowa state

2. Total sales of liquor of a single category for all the stores in descending order (Top 20)

We removed unwanted JOIN (Fig. 3.) from the query to optimize and fetch more efficient data from the table. Refer Fig. 15.

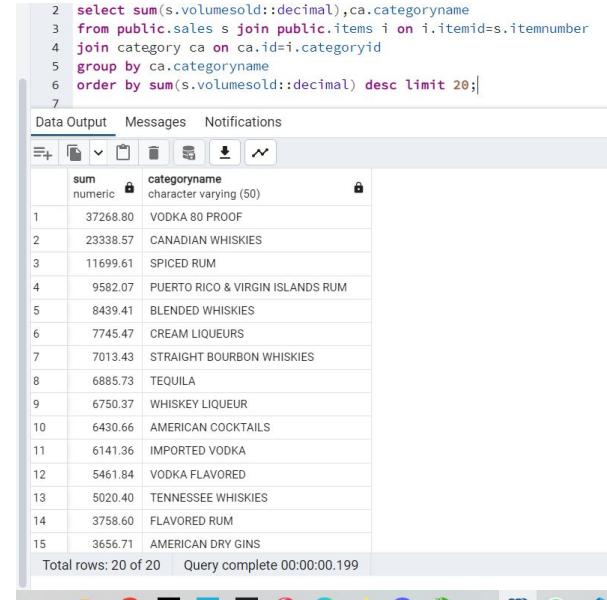

Fig. 15. Query Optimization: Total sales of liquor of a single category for all the stores in descending order

• Trigger:

Using TRIGGER, we delete the respective entry from Sales table when the entry from Store is deleted. We uses TRIGGER function in TRIGGER to invoke deletesales function after deleting entry from store. Refer Fig.16.

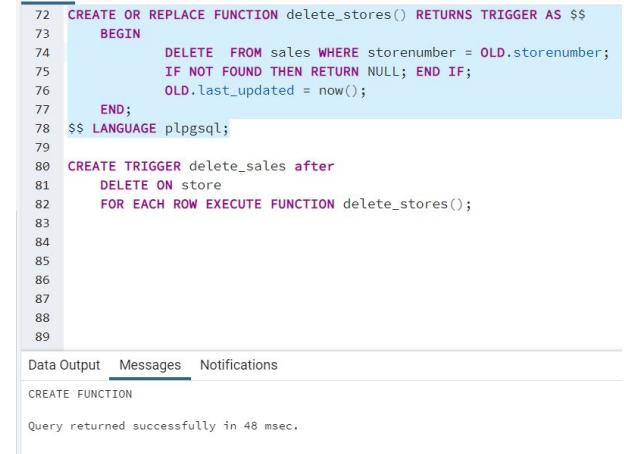

Fig. 16. Trigger

VII. COST CALCULATION OF QUERY

We used, EXPLAIN function to analyse the cost of each query. Refer Fig.17.

```

40 7.explain analyse
41 SELECT si.storename, sum(s.volumesold::decimal)
42 FROM SALES s ,store si
43 WHERE si.id=s.storenumber group by storename order by sum(s.volumesold::decimal) desc
44

```
